Elastic Post-buckling Stiffness of Rectangular Frames Using Perturbation Technique

Mohammad Z. Kabir*, Afshin Moslehi Tabar**

ABSTRACT

The post-buckling behavior of rectangular frames in elastic domain is studied in depth. In analysis, unsymmetrical geometry, sway possibility and support conditions are considered in order to find their influences on load-deflection path and non-linear deformations. The static perturbation technique is used for analysis and discussion. The first, second and third order perturbation problem, as an accuracy measurement, for the frame are solved and the solutions are compared with previously published papers. The results reveal that the symmetric frame with sway movement, due to non-axial force in beam, has symmetric bifurcation point in the first order perturbation analysis. However, the post-buckling behavior of un-symmetric frames with or without sway is bifurcated in an asymmetric manner.

KEYWORDS

Post-Buckling Behavior, Perturbation Technique, Nonlinear Deformation, Bifurcation.

1. INTRODUCTION

The analysis of elastic post-buckling behavior of frames is rather complicated since it necessitates a geometrically non-linear bending. The post-critical analysis of elastic structures invariably requires the solution of a set of non-linear differential equations and is based solely on equilibrium equations. Koiter [1] analyzed the post critical behavior of asymmetric bifurcation by power series expansion approach. Roorda [2] conducted model experiments, which confirmed Koiter’s calculations, particularly the reduction of a maximum load as a function of the initial imperfection in the form of load eccentricity. Roorda and Chilver [3] employed the perturbation method with power series expansions for analysis of non-linear equations. A nonlinear finite element analysis for frames is proposed by Care et al. [4]. The post-buckling behavior of perfect framed structures as well as the nonlinear geometric analysis of imperfect frames can be handled by this method. Since the nonlinear formulation is based on the incremental finite element procedure, frame elements have to be subdivided into a number of smaller segments to attain the required convergence. Bazant and Cedolin [5] adopted the stiffness matrix method and stability functions from linear theory and enhancing by additional terms to deal with the second order deformation in non-linear behavior. Ekhande et al. [6] studied the stability functions for three-dimensional beam-columns. They considered the effect of flexure on axial stiffness and the effect of axial force on flexural stiffness. The non-linearity of geometric stiffness matrix in their manipulation is limited to the first order. The present work employs the suggested static perturbation method, Roorda and Chilver [3], based on equilibrium and flexibility approach and by simple manipulations for higher order non-linear stability solutions for utilizing the behavior of rectangular frames with symmetric and non-symmetric geometry and applied loading. The main assumptions of coming analysis are based on frame continuity and straightness of slender members. The degree of instabilities at the onset of buckling in a frame is generally not high, and the purpose of the paper is not to suggest that this instability is important for practical purposes, but rather to show the application of non-linearity is extensively dependent on geometry of frame and the applied load configurations.

2. ANALYSIS

Consider a straight member $ij$ of length $l_{ij}$ and flexural stiffness $EI_i$ of a continuous, rigidly jointed plane frame.
The unbuckled states of the member, which is supposed to be axially rigid but flexible in bending, are sketched in Figure 1 along with the positive directions of the rotations $(\theta_x, \theta_y)$, chord rotation $(\varphi_y)$, end moments $(M_i, M_j)$, end shears $(Q_{ij})$ and axial force $(P_y)$.

![Figure 1: End forces and deflections of member $ij$.](image)

Now, for a portion of the beam of length $ds$ from end $i$ along with the deflected member as shown in Figure 2, the equilibrium conditions require:

![Figure 2: Equilibrium of a beam portion with length of $ds$.](image)

\[
EL_y \frac{d\theta}{ds} + P_y \int_0^s \sin \theta(s) \, ds + Q_y \int_0^s \cos \theta(s) \, ds + M_y = 0
\]

(1)

By differentiation of above equation with respect to $s$

\[
EL_y \frac{d^2\theta}{ds^2} + P_y \sin \theta(s) + Q_y \cos \theta(s) = 0
\]

(2)

From equilibrium of Figure 1, the following relations can be written

\[
Q_{ij} = \frac{M_i + M_j}{L_y - \lambda_y}; \quad Q_y = Q_{ij}; \quad P_y = P_{ij}
\]

(3)

$\lambda_y$ represents shortening of the member length due to buckling, and its value is obtained as follow

\[
e_y = L_y - \int_0^t \cos \theta(s) \, ds
\]

(4)

The boundary conditions of nonlinear differential equation are as follow:

\[
\left. \frac{d\theta}{ds} \right|_{s=0} = -\frac{M_i}{EL_y}; \quad \left. \frac{d\theta}{ds} \right|_{s=L_y} = \frac{M_j}{EL_y}
\]

(5)

For simplicity, the dimensionless quantities, $p_i, p_y, q_y,$ $m_y, n_y, x, \Lambda_y, \lambda_y$ are utilized in the following as defined in Appendix.

By appropriate substituting of normalized relations in (A-1a) to (A-H), see Appendix, the dimensionless form of (2) is rewritten

\[
\theta''(x) + p_y \sin \theta(x) - q_y \cos \theta(x) = 0
\]

(6)

with the boundary conditions:

\[
\theta(0) = -m_y; \quad \theta(1) = m_y
\]

(7)

and equilibrium equations as follow:

\[
q_y = \frac{m_y + m_j}{1 - \lambda_y}; \quad q_y = q_{ij}; \quad p_y = p_{ij}
\]

(8)

In this study the static perturbation technique is applied for the solution of nonlinear differential (6). For this respect, $\theta, p, q, m, n$ are expressed in power series form as functions of some parameter $\varepsilon$ which increases from zero along an equilibrium path leaving a known equilibrium point, see details in Appendix.

Before deriving the perturbation equations, it is convenient to eliminate $q_y$ using the equilibrium equation

\[
q_y(\varepsilon) = \frac{m_y(\varepsilon) + m_j(\varepsilon)}{1 - \lambda_y(\varepsilon)}
\]

(9)

where $\lambda_y$ is the dimensionless flexural shortening of the member which can be expressed as a series function of $\varepsilon$ as

\[
\lambda_y(\varepsilon) = \frac{\varepsilon^2}{2!} \int_0^1 \theta^2 \, dx + \frac{\varepsilon^3}{3!} \int_0^1 \theta^3 \, dx + \cdots
\]

(10)

By substituting (A-2) and (10) into (9), and equating terms of the same power in $\varepsilon$, yields

\[
\ddot{q}_y = \ddot{m}_y + \ddot{m}_j
\]

(11a)

\[
\ddot{q}_y = \ddot{m}_y + \ddot{m}_j
\]

(11b)

\[
\ddot{q}_y = \ddot{m}_y + \ddot{m}_j + 3(\dot{m}_y + \dot{m}_j) \int_0^1 \theta^2 \, dx
\]

(11c)

Finally, upon substitution of (A-2) and (9) in (6) and equating coefficients of same power of $\varepsilon$, the following infinite system of perturbation equations are obtained

\[
\ddot{\theta} + p_y \dot{\theta} = \dot{m}_y + \dot{m}_j
\]

(12a)

\[
\ddot{\theta} + p_y \dot{\theta} = \dot{m}_y + \dot{m}_j - 2p_y \dot{\theta}
\]

(12b)
\[ \ddot{\theta} + p_0 \ddot{\varphi} = \dot{m}_y + \dot{m}_\mu + 3(\dot{m}_y + \dot{m}_\mu) \int_0^1 \dot{\varphi}^2 \, dx - 3[\dot{p}_0 \ddot{\varphi} + \ddot{p}_0 \dot{\varphi} + (\dot{m}_y + \dot{m}_\mu) \dot{\varphi}^2] + p_0 \dot{\varphi} \]

whose respective boundary conditions become

At \( x=0 \):

\[ \dot{\theta} = -\dot{m}_y ; \quad \ddot{\theta} = -\ddot{m}_y ; \quad \dddot{\theta} = -\dddot{m}_y \]  

(13a)

At \( x=1 \):

\[ \dot{\theta} = -\dot{m}_y ; \quad \ddot{\theta} = -\ddot{m}_y ; \quad \dddot{\theta} = -\dddot{m}_y \]  

(13b)

The important point to note is that this infinite system can be solved recursively. For example, the determination of the nth order solution requires a knowledge of the solution of the 1st up to, and including, the (n-1)th order problems. At each step in the analysis, the solution of a non-homogeneous differential equation of the type

\[ \phi''(x) + p_0 \phi(x) = v(x) \]  

(14)

is subjected to the boundary conditions

\[ \phi(0) = -\mu_y ; \quad \phi'(1) = \mu_y \]  

(15)

is required. Using common methods for solution of the differential (14), differential (12) can be solved.

A. First order solution

The solution of (12-a) is as follow, [7]:

\[ \dot{\theta} = \frac{1}{p_0} (\dot{m}_y + \dot{m}_\mu) - \frac{1}{\sqrt{p_0}} \dot{m}_y \cot \sqrt{p_0} + \dot{m}_\mu \csc \sqrt{p_0} \cos \sqrt{p_0} x - \frac{1}{\sqrt{p_0}} \dot{m}_\mu \sin \sqrt{p_0} x \]  

(16)

By substituting \( x=0, \ x=1 \) in (16), \( \dot{\theta}_y \) and \( \dot{\theta}_\mu \) are determined, as

\[ \dot{\theta}_y = f_y \dot{m}_y + g_y \dot{m}_\mu \]  

(17a)

\[ \dot{\theta}_\mu = g_y \dot{m}_\mu + f_y \dot{m}_\mu \]  

(17b)

Coefficients of \( f_y \) and \( g_y \) are given in (18)

\[ f_y = \frac{1}{p_0} [1 - \sqrt{p_0} \cot \sqrt{p_0}] \]  

(18a)

\[ g_y = \frac{1}{p_0} [1 - \sqrt{p_0} \csc \sqrt{p_0}] \]  

(18b)

When axial force is zero (such as beams) extreme values of \( f_y \) and \( g_y \) are equal to

\[ f_y = \frac{1}{3} ; \quad g_y = -\frac{1}{6} \]  

(19)

B. Second order solution

The solution of (12-b) is as follow:

\[ \ddot{\theta} = \frac{1}{p_0} (\dot{m}_y + \dot{m}_\mu) - \frac{1}{\sqrt{p_0}} \dot{m}_y \cot \sqrt{p_0} + \dot{m}_\mu \csc \sqrt{p_0} \cos \sqrt{p_0} x - \frac{1}{\sqrt{p_0}} \dot{m}_\mu \sin \sqrt{p_0} x \]  

\[ \dot{\varphi} \]  

\[ \frac{\sqrt{p_0}}{p_0} \left[ (\dot{m}_y + \dot{m}_\mu) \right] - [\dot{m}_y \cot \sqrt{p_0} + \dot{m}_\mu \csc \sqrt{p_0} \cos \sqrt{p_0} x - \frac{1}{\sqrt{p_0}} \dot{m}_\mu \sin \sqrt{p_0} x \]  

\[ \frac{\sqrt{p_0}}{p_0} \left[ (\dot{m}_y + \dot{m}_\mu) \right] - [\dot{m}_y \cot \sqrt{p_0} + \dot{m}_\mu \csc \sqrt{p_0} \cos \sqrt{p_0} x - \frac{1}{\sqrt{p_0}} \dot{m}_\mu \sin \sqrt{p_0} x \]  

\[ \frac{\sqrt{p_0}}{p_0} \left[ (\dot{m}_y + \dot{m}_\mu) \right] - [\dot{m}_y \cot \sqrt{p_0} + \dot{m}_\mu \csc \sqrt{p_0} \cos \sqrt{p_0} x - \frac{1}{\sqrt{p_0}} \dot{m}_\mu \sin \sqrt{p_0} x \]  

(20)

Substituting \( x=0 \) and \( x=1 \) in (20), \( \ddot{\varphi}_y \) and \( \ddot{\varphi}_\mu \) are determined, respectively

\[ \ddot{\varphi}_y = f_y \ddot{m}_y + g_y \ddot{m}_\mu + 2 \dot{p}_y (F_y \dot{m}_y + G_y \dot{m}_\mu) \]  

(21a)

\[ \ddot{\varphi}_\mu = g_y \ddot{m}_\mu + f_y \ddot{m}_\mu + 2 \dot{p}_y (G_y \dot{m}_\mu + F_y \dot{m}_\mu) \]  

(21b)

where

\[ F_y = -\frac{1}{2} \frac{1}{p_0} \left[ \frac{2}{p_0} - \cot \sqrt{p_0} \left( \cot \sqrt{p_0} + \frac{1}{\sqrt{p_0}} \right) - 1 \right] \]  

\[ G_y = -\frac{1}{2} \frac{1}{p_0} \left[ \frac{2}{p_0} - \csc \sqrt{p_0} \left( \cot \sqrt{p_0} + \frac{1}{\sqrt{p_0}} \right) \right] \]  

(22)

in the absence of axial force

\[ F_y \]  

\[ G_y = -\frac{7}{360} \]  

(23)

Finally, considering (A-2.1) and (10), one can write

\[ \ddot{\varphi}_0 = (\dot{m}_y + \dot{m}_\mu) F_y + 2 \dot{m}_y \dot{m}_\mu G_y \]  

(24)

3. Stability of Frames

Frames generally consist of a number of beam-
columns. As a result, to study buckling of frames, beam-column relations are applied, however, boundary conditions are no longer as simple as those of beam-columns. To analyze frames, a series of extra equations are needed. Followings are short reviewing of these equations.

A. Equilibrium of a joint

Consider two transverse members which are joined at the point (i) as shown in Figure (3).

Figure 3. Positive forces and deformations in a joint

Two equilibrium equations in x and y directions are written as

\[-c_i \cos \phi_i - \sum n_j p_{ji} \cos(\gamma_j + \phi_j) - \sum n_k q_{ki} \sin(\gamma_k + \phi_k) = 0\]  
\[-c_i \sin \phi_i - \sum n_j p_{ji} \sin(\gamma_j + \phi_j) - \sum n_k q_{ki} \cos(\gamma_k + \phi_k) = 0\]  
\[s_o m_o + s_a m_a + \cdots = 0\]  

(25a)

(25b)

(25c)

B. Continuity of joint rotation

Continuity of joint rotation, as shown in Figure 4, is written as:

\[\theta_o - \varphi_o = \theta_a - \varphi_a = \theta_o - \varphi_o\]  

(26)

Figure 4. Rotation in a joint

C. Deformation compatibility equation in a closed loop

Consider a closed loop as shown in Figure 5 solid and dashed lines show the undeformed and deformed shape, respectively. Geometry of loops indicate

\[\sum A_i (1 - \lambda_i) \cos(\gamma_i + \varphi_i) = 0\]  
\[\sum A_i (1 - \lambda_i) \sin(\gamma_i + \varphi_i) = 0\]  

(27a)

(27b)

Figure 5. Deformed and undeformed configuration of a closed frame.

In the following, the post-buckling behavior of a number of frames with typical specifications including: sway possibility, boundary conditions, frame symmetry or asymmetry and relative stiffness of beams, columns is investigated by means of the method described earlier.

4. A FRAME WITH SIDE-SWAY

Consider a side-sway permitted frame that is generally asymmetric, as shown in Figure 6. The asymmetry was induced by taking different columns length. Conventional positive deformations are shown in the figure.

Figure 6. Frame with side-sway

By making use of compatibility equations of the closed loop as well as equilibrium conditions of the joints 2 and 3, following equation is resulted in,

\[\Phi_{12} = \frac{\alpha \Phi_{34}}{(1 + \alpha k)^2} \left[ n_{12} + \frac{1}{\alpha^2} n_{34} \right] \]  

(28a)
\[ \dot{\phi}_{12} + \dot{\phi}_{34} = \frac{1}{k} \ddot{m}_{21} + \frac{1}{\alpha^2} \dddot{m}_{34} - 2 \dot{p}_{12} \dot{\phi}_{12} - \frac{2}{\alpha^2} \dddot{p}_{34} \dot{\phi}_{34} \]  

(28b)  

In addition, from continuity conditions of the joints 2 and 3, two series of key equations can be readily achieved, as follows,  

\[ \ddot{\theta}_{12} - \ddot{\theta}_{32} = \ddot{\theta}_{23} \]  

(29a)  

\[ \ddot{\theta}_{34} - \ddot{\theta}_{32} = \ddot{\theta}_{43} \]  

(29b)  

Upon substitution of (33) and (28) in (29) results in:  

\[ f_{12} + \frac{1}{3} \frac{\alpha}{(1+\alpha)k} \dddot{m}_{21} - \frac{1}{6\alpha} + \frac{1}{\alpha(1+\alpha)k} \dddot{m}_{34} = U(k, \dot{m}_{31}) \]  

(34a)  

\[ f_{34} + \frac{1}{3} \frac{\alpha}{(1+\alpha)k} \dddot{m}_{34} - \frac{1}{6\alpha} + \frac{1}{\alpha(1+\alpha)k} \dddot{m}_{34} = V(k, \dot{m}_{31}) \]  

(34b)  

Coefficients of (34) are exactly similar to those of (31) that the determinant of coefficients is zero in critical load. If the solutions \{ \dot{m}_{31}, \ddot{m}_{34} \} are to be finite, then by Cramer’s rule, the determinant obtained by replacing any column of coefficient by \{ U, V \} must also be zero.

\[ \begin{vmatrix} f_{12} + \frac{1}{3} \frac{\alpha}{(1+\alpha)k} & U \\ f_{34} + \frac{1}{3} \frac{\alpha}{(1+\alpha)k} & V \end{vmatrix} = 0 \]  

(35)  

To illustrate the implementation of the static perturbation method, the post-buckling analysis of the frame shown in Figure 6 has been involved in Appendix and in the following just the results are mentioned. Numerical results of (32) and (35) for various values of \( \alpha \) are given in Table 1, and also they are depicted in Figure 7.

Amirkabir/ Vol. 16/ No. 62-C/( Civil Engineering)/ Summer-Fall 2005
The results, in the case of \( \alpha = 0 \), coincide to the results obtained by Roorda (1965). Because the buckling directions of the frame for \( \alpha = 0 \), 2 are different, their post-buckling slopes are on the contrary. It should be noted that in the case of \( \alpha = 1 \), the first order axial load in beam becomes zero, consequently, the post-buckling path in this case is symmetric bifurcation, whereas in the other cases, the first order axial load in the beam 2-3 is exist, so post-buckling paths are asymmetric.

5. A FRAME WITHOUT SIDE-SWAY

A. Hinged supports

Consider a symmetric side-sway prevented frame in which the length and flexural stiffness of beam are \( \alpha \), \( \beta \) times those of columns, respectively. Simply supports are considered for the frame. Initial frame and conventional positive deformations are shown in Figure 8.

The procedure of analysis is similar to previous example, except that symmetry properties can be used. In the following, merely final results are mentioned. Characteristic equation is obtained as, [7]:

\[
f_{12} + \frac{\alpha}{2\beta} = 0
\]

and, the equation of post-buckling path becomes

\[
k = -\frac{\alpha^2}{16\beta f_{12}F_{12}}\dot{\theta}_{21}, \quad (k = k_{cr})
\]

(37)

Numerical results of (36) and (37) for various values of \( \alpha \) and \( \beta \) are given in Tables 2 and they are also depicted in Figure 9.

\[
k = \frac{\alpha}{1.54k_{cr}}
\]

\[
\dot{\theta}_{21}
\]

B. Fixed supports

Now consider the previous example (case A) with fixed supports, Figure 10, the only difference between these two cases is that rotations of supports are equal to zero.
Characteristic equation of critical load is

\[ f_{12}^2 - g_{12}^2 + \frac{\alpha}{2\beta} f_{12} = 0 \]  

(38)

and the of post-buckling path becomes

\[ k = \frac{1}{24} \frac{\alpha^3}{\beta^2} \frac{f_{12}}{f_{12}^2 - g_{12}^2} \times \frac{3}{2} \frac{8_{12}}{f_{12}} \frac{G_{12} - f_{12}G_{12}}{f_{12}^3} \frac{F_{12}G_{12} - G_{13}G_{12}}{f_{12}} \phi_{21} \]  

(39)

Numerical results of (38), (39) for various values of \( \alpha \) and \( \beta \) are given in Table 3, and also they are depicted in Figure 11.

### 6. CONCLUSIONS

In this paper, the non-linear post-buckling behavior of rectangular plane frames is analyzed using the standard procedure of the static perturbation technique. The solution of a highly non-linear problem is reduced to the recursive solution of an infinite set of linear problems. Based on parametric studies made in this study, the following remarkable conclusions are pointed out:

1. In the stability of symmetrical portal frames with permitted sway, due to zeroes of axial force in the beam resulted from the first order non-linear analysis, the post buckling of frame becomes unstable. But, at the second order analysis of the beam, axial force is exist and make stable post-buckling of the frame.
2. The post-buckling behavior of non-symmetrical frames is stable, due to tensile force in the beam.
3. In portal frames, when sway is not permitted, the potential loading of frames beyond buckling is reduced due to compressive force in the beam and decreasing of total frame stiffness.
4. Reducing ratio of \( S_B/S_c \), \( S_B \) and \( S_c \) are beam and column stiffness, respectively, improves the post-buckling

(Case II-B)
behavior in sway permitted frames and weakens this capacity in non-permitted sway frames.

5. The influence of support conditions on the post-buckling stiffness of frames is revealed in that sway-permitted frames, the simple supports reactions improve post-buckling stiffness rather than fixed supports.

7. APPENDIX

The dimensionless quantities, $p$, $q$, $m$, $n$, $x$, $y$, $\lambda$, are defined as follows:

$$ P_i = k_i \left( \frac{L^2}{EI} \right)_{REF}; \quad (P_i \text{ is external force and } k_i \text{ is load factor}) $$

$$ p_i = p_i \left( \frac{L^2}{EI} \right)_{REF} \quad (A-1a) $$

$$ q_i = Q_i \left( \frac{L^2}{EI} \right)_{REF} \quad (A-1b) $$

$$ m_i = M_i \left( \frac{L}{E} \right)_{REF} \quad (A-1c) $$

$$ n_i = \frac{(EI/L^2)_{REF}}{(EI/L^2)_{REF}} \quad (A-1d) $$

$$ x = s / L \quad (A-1e) $$

$$ s_i = \frac{(EI/L)_{REF}}{(EI/L)_{REF}} \quad (A-1f) $$

$$ A_i = \frac{L}{L_{REF}} \quad (A-1g) $$

$$ \lambda_i = \frac{\varepsilon_i}{L_i} \quad (A-1h) $$

To apply the static perturbation technique for the solution of (6), suppose that $\theta$, $p$, $q$, $m$, and $n$ can be expressed in power series form as functions of some parameter $\varepsilon$ which increases from zero along an equilibrium path leaving a known equilibrium point. Starting from the un-deflected configuration, and allowing the possibility of an un-buckled configuration at finite values of $p$, one can set:

$$ p_i(\varepsilon) = p_i + \varepsilon \dot{p}_i + \frac{\varepsilon^2}{2!} \ddot{p}_i + \cdots \quad (A-2a) $$

$$ q_i(\varepsilon) = q_i + \varepsilon \dot{q}_i + \frac{\varepsilon^2}{2!} \ddot{q}_i + \cdots \quad (A-2b) $$

$$ m_i(\varepsilon) = m_i + \varepsilon \dot{m}_i + \frac{\varepsilon^2}{2!} \ddot{m}_i + \cdots \quad (A-2c) $$

$$ n_i(\varepsilon) = n_i + \varepsilon \dot{n}_i + \frac{\varepsilon^2}{2!} \ddot{n}_i + \cdots \quad (A-2d) $$

$$ m_i(\varepsilon) = m_i + \varepsilon \dot{m}_i + \frac{\varepsilon^2}{2!} \ddot{m}_i + \cdots \quad (A-2e) $$

$$ m_i(\varepsilon) = m_i + \varepsilon \dot{m}_i + \frac{\varepsilon^2}{2!} \ddot{m}_i + \cdots \quad (A-2f) $$

$$ \phi_i(\varepsilon) = \phi_i + \varepsilon \dot{\phi}_i + \frac{\varepsilon^2}{2!} \ddot{\phi}_i + \cdots \quad (A-2g) $$

$$ \lambda_i(\varepsilon) = \lambda_i + \varepsilon \dot{\lambda}_i + \frac{\varepsilon^2}{2!} \ddot{\lambda}_i + \cdots \quad (A-2h) $$

$\varepsilon$ is a small parameter and becomes zero at the unbuckled configuration. It is increased along load-deflection path. In above equations, dots indicate differentiation with respect to $\varepsilon$.
